Abstract: The economic and social environment caused by the COVID-19 pandemic has brought additional pressure on supply chains because they now have more pressure to develop and adapt to a context of economic constraint. Delays in the supply chain can bring consequences such as the lack of food products by retailers, transporters and manufacturers. Thus, this study aims to examine the supply chain during the COVID-19 pandemic in small- and medium-sized food companies in the central region of Portugal, identifying potential problems and pointing out the respective solutions. For this purpose, the study uses a qualitative methodology through semi-structured interviews. It was found that small and medium-sized enterprises (SMEs) do not have a codified supply chain and that generally, these companies have a minimal budget, which requires a constant search for new suppliers that represent a reduction in costs. Moreover, most of the companies surveyed faced unexpected challenges, such as a lack of alternative suppliers. The present paper is original because it studies the supply chain in SMEs in the food sector during the COVID-19 pandemic, and it allows the ascertainment of practical suggestions for these companies to improve, as well as contributing to the clarification of the literature on the supply chain in times of crisis such as the current COVID-19 pandemic.

Keywords: supply chain disruptions; SARS-CoV-2/COVID-19 pandemic; small and medium food businesses; supply chain vulnerability and resilience

1. Introduction

A business model is understood as a structure composed of elements, interconnections and dynamics. The Complex Adaptive System (CAS) is one of the most advanced examples of systems theory. The addition of sophistication, flexibility and adaptation allows a CAS to reflect a business model [1]. A business model is composed of eight related resources, including resilience and adaptability, that lie at the boundaries of an organisation [1,2]. The phrase “adaptability causes uncertainty” is central to complex adaptive system (CAS) theory [3]. Stability within organisations through supply chains recognises the ability to withstand shocks in the form of severe events, and companies must establish constructive and reactive behaviour to acquire resilient capabilities to achieve this; that is, to be able to respond effectively to disasters that may occur [4]. The threat of supply disruptions must be considered in contemporary supply chain management. Supply chain delays usually arise with low probability, and however, even if they happen occasionally, they can bring severe consequences to companies [5]. Some researchers have resorted to using expected disruption cost (EDC) as a preparedness tool or metric [6].

Due to the COVID-19 pandemic, supply chains were forced to evolve and learn how to respond to this new society that presents dynamics of increased closure, isolation and

restrictions on social and economic interactions. The restrictions imposed to prevent the spread of the virus directly affected the global economy and, consequently, the movement of goods. Pandemics and outbreaks, such as the COVID-19 virus, are possible causes of supply chain disruption [7]. As a result of this context, there have been negative impacts on world trade, with supply chains almost stopping their regular activity altogether. Among the disruptions that result from this, we can include delivery delays and labour shortages. Supply chain managers are aware that materials and commodities necessary to the business are in short supply worldwide. Supply disruptions should be included in current supply chain management and companies should plan their supply chains extensively [8]. They should also focus on keeping resilience balanced with efficiency and cost reduction to predict supply disruptions. The occurrences caused by the COVID-19 pandemic indicate a wide range of risks in the supply chain, where sudden instability affects its long-term development [7].

This study presents as a starting question “What are the most prevalent indicators of disruption, vulnerability and resilience in the supply chain in pandemic times” and focuses on deepening the knowledge about the supply chain when it is in a vulnerable position, either because of the effect of environmental or pandemic crises [9] or because it is in a situation of disruption. We also seek to understand how these companies can be resilient when they encounter these contexts. We analysed the supply chain of five companies in the food sector in Portugal.

Concerning the issues investigated in this work, the selection of suppliers and the ability of those responsible for considering their decision-making are factors considered conducive so that some kind of disruption occurs in the supply chain [5]. In the present study, it was possible to ascertain that supply chain vulnerability received little attention in the literature [10] and that a relationship of an environmental and anthropogenic nature, related to market volatility, prevails, since a notion is felt that a system will recover its initial state after the effect of the factors that affected it [4].

The main results are taken from this study point in the direction that the pandemic that we are going through has dramatically affected these companies’ supply chains because they have suffered stock shortages due to the delayed arrival of products in this period. Finally, the companies have relatively low budgets, so they have to search for suppliers according to their budget, which ends up causing obstacles in creating long-term relationships.

However, there are limitations in this study, which prevent us from extracting the maximum knowledge from this subject. The current research was conducted in specific sectors and a particular context. For this very reason, we must limit ourselves to the unique circumstances and refrain from generalising the conclusions. Finally, we point out that the difficulty in defining the customer can be resolved by using a cause–effect relationship system [1].

This paper is structured as follows: It starts with the introduction, which is Section 1 of the article, to present the topic to be discussed. This is followed by a literature review in Section 2, which addresses the issue under study to familiarise the reader with it, address relevant concepts and explore theories. Section 3 presents the methodology followed in this study, and Section 4 presents and discusses the results. Finally, in Section 5, a brief conclusion is shown, where the main results obtained are explained.

2. Literature Review

2.1. Complex Adaptive System Theory

The term “complexity” originated from the Latin “complexus”, which means multiple elements. However, some authors consider that the word comes from the Latin “plexus”, which ends up meeting Tronca’s understanding. This term in Latin means connected. Complexity science refers to a subset of all systems, which are called complex systems. The individual and causal study in these systems are described as trivial. That is, a broad perspective is needed to understand the unpredictability embedded in complex systems.

To facilitate understanding of these systems, complexity science provides complex adaptive systems as support [3,11,12].

A complex adaptive system is made up of several components that communicate with each other. When a mechanism evolves and communicates with the environment, its behaviour changes. The theory studies the characteristics of systems, such as self-organisation and adaptation [13–15]. This system is understood to be the suitable model to discuss the complexity present in social sciences today. It is understood as an efficient system that can structure its basic format by resorting to exchanging resources integrated into its environment. They are also able to shape these resources to support action. These systems are usually characterised by path dependency, disorganisation, contingency and adaptability [3,15].

Complexity Theory is a modern way of interpreting current problems [12]. Complex adaptive system (CAS) theory was established in associated studies [3]. Edgar Morin is a vital complexity researcher today who proposed a change in the information model through paradigms of interknowledge in history, geography and law [12]. The author was the first to demonstrate the complexity procedure, starting from his model “Unity in diversity” (1973). This was followed by a Belgian scientist, Prigogine, who introduced “complexity science” [16].

In 1984, the Santa Fe Institute acquired the concept as a slogan and suggested that “adaptability creates complexity.” In 1994, the same year that the institute celebrated its 10th anniversary, the development of the complex adaptive system theory was made official by Professor Holland [3]. Equilibrium and predictability are the exceptions, as contemporary research has shown through Complexity Theory. This theory justifies these nonlinear processes, allowing a deeper interpretation of order-disorder equilibrium [14,15].

Real-time planning is a form of complexity theory and allows for real-time predictions [15]. The purpose of CAS theory has broadened from the biological sciences to the social sciences due to its development. This theory is understood to be suitable for analysing decision-making mechanisms and the influence of the interaction of multiple participants [16]. Complexity Theory was referred to as a potential new concept in science [12].

In this theory, due to the relationships/interactions and the new information created by them, the concept of unpredictability appears [11]. As said before, the meaning of this theory focuses on the expression of “adaptability creates complexity,” and it presents two levels: micro and macro. As for the micro-level, the individual and the environment can instruct each other using mutual interaction, while at the macro level, the behaviour taken by the subject impacts the environment, which is constantly changing, ultimately limiting the subject’s behaviour [16]. After the 1960s, internal and external conditions became increasingly dynamic, putting enormous pressure on business, especially in strategy. Corporations then began to seek flexible, innovative and multi-skilled employees [15].

Wang, Dong, Zhang and Luo [16] drew upon the theory in question, using it as a basis for analysing the matter of low resilience regarding the management of adversity in community public health. These authors emphasise that this theory is applied as a support because of its ability to highlight the relationship between individuals and the environment to improve adaptability to the environment. In the same study, it is suggested to institute a model for community multicultural relationship resilience using the complex adaptive system theory to extend the level of resilience [16]. Some studies aggregate this theory together with fashion [12] and others that refer, in their themes, the theory involved with different companies, applying it to the perspectives of their organisational environment [15].

2.2. Business Supply Chain Disruptions

According to the authors, Fahimnia, et al. [17], supply chain managers are subjected to new challenges, such as building a supply chain network that is effective, efficient and resilient enough to overcome disruptions. However, at the same time, it must be sustainable [18]. These disruptions can be caused by natural phenomena such as earthquakes,

tsunamis and bad weather, or by the hand of humans [19]. For this reason, the authors also mentioned that supply chain groups tend to deviate from their sustainability purposes while dealing with unpredictable disruption [6].

Authors Sureeyatanapas, Waleekhajornlert, Arunyanart and Niyamosoth [5] agreed that disruptions regarding supply disruptions are expanding among companies. However, with the pandemic that the world is currently experiencing, supply chains have been forced to adapt and adjust to this new closed world. Consequently, a worldwide shortage of essential products and goods has occurred [8]. These events forced companies to change their management and logic in supply chains, alerting them to the changes that needed to be applied if disruptive events of the same kind happened again [8]. Some authors suggest companies perform extensive mapping of their supply chains so that it is possible to predict and anticipate supply-side disruptions [8,20].

Thus, the threat of supply disruptions must be considered in modern supply chain management [21]. Suppose the danger of disruption is related to the supplier choice issue. In that case, it will be unwise to assume that complete data about all the criteria or the complete understanding of the decision-maker regarding the problem are available. The occurrences of disruptive phenomena usually occur with low probability but with high intensity and can be seen as ambiguities concerning the supply chain system [5].

Some authors resorted to using EDC (expected disruption cost) as a metric for planning a resilient supply chain network [22]. For example, suppose there is any supplier that is susceptible to outages. In that case, the responsible individual may choose to go for another one without considering the sustainability factor, i.e., decreasing the risk of outages [6].

Even though the feasibility of disruptions is hard to assess, Lim, et al. [23] concluded that devaluing the probability of disruptions comes out to be more risky/dangerous than overestimating the chance (Mari et al., 2014). The way to maintain a handle on these costs of disruptions, supply chain costs and others is to perform an approach grounded in multi-objective goal planning [6].

2.3. Vulnerability in the Supply Chain

In our study, we considered that vulnerability is a variable formed on the outside, and through the size of an impact, or even some kind of damage, it can determine the risk [10]. Associated with the supply chain, it aims to demonstrate the extent to which it is exposed to a disruptive event [24]. Therefore, the vulnerability in the supply chain can be seen when a value movement, if it is exogenous, allows flexibility and can determine the value of product delay [25] and in a product or even during an information-sharing process. However, we can also find it in intangible assets (hardware, software, infrastructure and relations with other companies), as well as in the environment (political issues, such as economic, social, or technological [9].

The risk of inherent invulnerability is found when an interruption is determined. This risk and the ability to withstand a shock and strengthen the supply chain are characteristics by which vulnerability is defined [10]. In this regard, it was necessary to analyse the components (vulnerability and risk) in the case of a disruption. Thus, a graph theory was defined [26].

After the analysis of the components [26], some practices seek to combat vulnerability in the supply chain, such as: proactively manage the risks that the supply chain is subject to, and for this entrepreneurs will need to have methods to identify and measure the possible vulnerabilities, so that they can change factors that coincide with the expected compensation, in terms of risk-reward [27,28]. In a study conducted on the Toyota company, it was clarified that vulnerability might be lower, upon an interruption, if a node degree level (supply chain, in which the network has nodes) is associated with a power law in a supply network structure [26,29].

The concept of resilience, identified as an alternative to control some risks, was studied and worked on in the literature, unlike the little-discussed vulnerability. They only learn to

consider and quantify its index and guide the processes involved in optimising the value related to revenue [10,30].

2.4. Resilience in the Supply Chain

The word resilience originally comes from materials science. This refers to the ability of a system to recover its initial state after undergoing an elastic deformation without any changes in its nature [31]. Due to market instability, environmental problems and manufactured disasters, the importance of incorporating this concept was emphasised in the operations management scenario [32]. In operations management, resilience is defined as organisational capabilities to face immediate changes in the environment with proactive and reactive actions [33,34].

The first broad study on supply chain resilience began in the UK following transport disruptions due to fuel protests in 2000 and the foot and mouth disease outbreak in early 2001 [35]. The study explored the UK industrial knowledge base on supply chain vulnerabilities and found that: supply chain vulnerability is a major business issue, there is little research on supply chain vulnerability, awareness of the issue is weak and a methodology is needed to manage supply chain vulnerability [35].

Based on this empirical research, Christopher and Peck [36] developed an initial framework for a resilient supply chain. These authors stated that supply chain resilience could be created according to four key principles: (1) resilience can be built into a system before a disruption, (2) a high level of collaboration is required to identify and manage risks, (3) agility is essential to react quickly to unforeseen events and (4) risk management culture is a necessity. Characteristics such as agility, availability, efficiency, flexibility, redundancy, speed and visibility were treated as secondary factors [37].

Given that almost every supply chain faces disruptions of severity and various types, it is important to be prepared for any future disruptive event [38,39]. In a way that allows companies to respond efficiently and effectively and therefore become less vulnerable to disruptions [40]. Therefore, resilience within organisations and across supply chains recognises the ability to absorb shocks in the form of extreme events and the adaptive capacity to adjust to new circumstances and is then recognised as a response capability for a firm's performance as well as a key dimension for a firm's survival [4,41,42].

However, not all risks and impacts are predictable. In this way, if an interruption in the flow of goods or information occurs, there must be an immediate and effective response to minimise losses [36,43,44]. In this sense, to obtain adaptive capabilities to better respond to disasters, companies must develop proactive and reactive actions to overcome the impacts and remain competitive [42].

2.5. The Relationship between Adaptive System Complexity and Supply Chain Disruption, Vulnerability and Resilience

Supply chain resilience is related to disruption, vulnerability and the balance of recovery and resilience strategies [45–47].

Although several scholars have framed the collection of elements that make up a business model as a system [2], unfortunately, general system theory and system dynamics cannot model the true complexity of the business. That said, related constructs inevitably lack the attributes needed to explain this complexity and dynamism [1].

One of the most evolved forms of systems theory—the Complex Resilient Adaptive System (RCAS)—is proactively employed to prescribe the key considerations that must be addressed in a business model [1].

The introduction of complexity, resilience and adaptation allows an RCAS to represent a business model more accurately than general system theory, with strong alignment between the characterisation of an RCAS and the characteristics of a business environment [1]. Afuah and Tucci [2] defined a business model as a “system made of components, links between components, and dynamics”. Andersson, et al. [48] also considered business models in terms of agents, activities and resource exchanges between them, employing goal modelling from the business and information systems school of thought [1]. Itami and

Nishino [49] believed that a business model comprises two elements: a business system and a profit model [1]. Baden-Fuller and Haefliger [50] defined the business model as a system involving cause and effect relationships that identify who the customer is, engage with their needs, deliver satisfaction and monetise value [1]. Gassmann, et al. [51] viewed the business model as a system, adopting a systems lens as a theoretical framework to articulate how business model evolution occurs.

The systems theory has framed the notion of resilience as, for example, in resilient infrastructure systems, the ability of an entity or system to return to a normal condition after the occurrence of an event that interrupts its state [52], or perhaps more strategically, to the measure of a system and the ability to absorb ongoing, unpredictable change and still maintain its vital functions [1].

Finally, we consider in this study that a business model is a complex, resilient, adaptive system (RCAS) that is structured in the form of eight interconnected elementary functions, including resilience and adaptation, positioned within the boundaries of an enterprise, which operate in a feedback loop to create and manage value exchange [1].

3. Methodology

This qualitative study analyses the supply chain in vulnerable interruption situations resulting from the current pandemic context. It also analyses these companies' disruption, vulnerability and resilience to overcome the difficulties arising from this context within their supply chains. A qualitative study was suitable for the present research because observation in natural environments, in this case, allows interpretation and research phenomena such as the functioning of supply chains to understand the processes in the daily life of these companies. Thus, the qualitative method was suitable for this study. It requires a lot of effort and time to analyse the data collected through the interviews because it is a complex phenomenon [53–55].

The present study is a multiple case study where we applied semi-structured interviews previously used by Yaroson, Breen, Hou and Sowter [47]. The interviews lasted an average of 40 min. The type of sampling is non-probability by convenience because, for the study, we only considered companies in the central region of Portugal, which is a low-density region, as well as food companies. The strategy used for this study was cross-analysis, taking into account that it is guided by variables with characteristics that do not have quantitative values [55,56].

The companies in this study are SMEs. This aspect is reflected in the data provided by the Pordata platform, as it shows us a higher value, in terms of size, for SMEs than for large companies in Portugal (Table 1). However, the sectors, namely agriculture, manufacturing and restaurants, where these companies are included are in the group of sectors with larger sizes compared to the other sectors. Companies operating in these sectors suffered severe constraints at the various levels of their operations or logistics when the COVID-19 pandemic emerged and its social and economic consequences took hold. The lack of availability of food goods by retailers, transporters and manufacturers has brought consequences such as delays in the supply chain, with almost immediate practical consequences on quality of life and access to consumer goods by the general population, by that the selection of these SMEs becomes even more relevant.

Table 1. Size of companies and weight of corporations and sole proprietorships in Portugal.

	Large Enterprises	SME
2019	1357	1,333,649
	Companies	Individuals

4. Results and Discussion of the Results

Supply chain disruptions in companies can happen due to environmental factors and human nature [6]. That said, the supply chain, after a disruption, becomes vulnerable [9] and thus needs to recover from these situations, so it needs to be resilient [4].

4.1. Supply Chain Disruptions

In Table 3, we can see the results in the theme of supply chain disruptions. The delay in these companies is mostly due to the lack of supply of a food product by suppliers, transporters and producers (C, D, E); the closing of the borders between France and England due to Brexit (in the case of Company B); and due to epidemiological issues (Company A, there was a lack of important protein for the confection of the final product). This delay takes at least five days to three weeks (Company A, B, D, E); only Company C mentions that the product delay happens intermittently due to pandemic issues. In this study, the COVID-19 pandemic was identified as one of the main obstacles, and in the literature, it is also possible to verify its impact on product shortages [8,57,58].

Table 3. Synthesis of results of supply chain disruptions.

	Timing of Product Supply Delay	Duration and Reason for the Delay	The Quickness of the Perception of the Interruption/the Reason That Caused It	Alert Metrics in a Disruptive Event	Quick Perception of the Impact of the Interruption	Perceived Impact on Areas of the Supply Chain	Barrier Encountered during the Interruption
Company A	Lack of protein	- 3 weeks - COVID-19	2 days	Early warning from the wholesaler	Instantaneous	Raw materials sales area	Lack of suppliers of the same raw material
Company B	Fresh product delay	- 2 weeks - Brexit	- Immediately	No metrics of any kind	1 day	Sales area	Demand from customers, other suppliers
Company C	Bovine animal protein delay	- Intermittent delay - Bovine spongiform encephalopathy disease	- Immediately	No metrics at all	Immediately	Sales area	Fear in beef consumption
Company D	Vegetable product delays	- 5 days - Product production delay	2 days	Producer early warning	Immediately	Operating area	Reaching alternative producers
Company E	Flour product delay	- 5 days - Delay in flour transportation	- Immediately	Supplier early warning	At the time	Operating area	Finding a flour supplier

Moreover, in Table 3, it is possible to verify that almost all companies have early warnings as a metric. Only Company C mentions not having any metrics. Companies are discerning the interruption's impact; only Company B takes a day to realise it. They mostly perceive the impact on the sales areas, and Companies D and E refer to the operational area. In the literature, it is also possible to verify metrics, namely the expected cost of interruption, regarding chain planning [6] of risk detection visibility and learning [59,60].

The barriers found in Table 3 for the resolution of the interruption are the lack of alternative suppliers that ensure the same quality (Company A, D, E): one company refers to the fear of not consuming the products they sell (Company C) and Company B refers to the search for new suppliers by customers, which we can see is that it does not allow companies to have close and lasting relationships with suppliers, and this aspect would be very beneficial since it could produce high-quality products [58,61].

The supply chain can be exposed to some disruptive situation, creating a certain vulnerability [24], which can be countered through practices, such as proactive management [28].

4.2. Supply Chain Vulnerabilities

Table 4 addresses the theme of supply chain vulnerability, companies characterise their products as perishable products, with possibilities for innovation, as in the example of Company A, which intends to innovate in faster machines to decrease the time of confection of the final product and allows the competitiveness of the company to be increased [62,63].

Moreover, in Table 4, regarding the supply chain, for all companies present, there is almost always the same record of a process initiated by pre-defined contracts with suppliers, then the products are delivered by a carrier, after receipt they are stored, some are processed, others resold until they reach the final consumer. The companies provide directly to the final consumer, and only one delivers by own transport to customers, who promptly sell to the final consumer. The literature also mentioned, in addition to production, optimising maintenance and control to decrease costs [64].

Three companies present amplifying resources; in Table 4, A, D and E, refer to the product shelf life as a resource that amplifies the disruptive activities. Company A still refers to the margin of error of the human factor in the confection of the product, and companies B and C refer to not having amplifying resources. The issue of amplifying stock variation can bring instability, resulting from supply chain dynamics [65].

Four companies report that communication, embedded in management, with the other supply chain members is an asset for the company in a disruption. Only Company D does not consider that its management decision affects a disorder. This internal communication issue is also seen in the literature as a competitive advantage [66].

From both the role of suppliers in a disruptive activity and their role at the time of that activity, only one company stated that suppliers have a function, and that function is to deliver the products needed to achieve that innovation. They exemplified the incremental innovation of the sweet "fradinhos", in which they had to ask suppliers for the products needed for its confection, and again allows a competitive advantage [62,63].

Finally, all the companies refer that the regulatory bodies supervise and inspect the company to provide safety to the final consumers. Two of the companies refer to the ASAE. One refers to GRASP, and one refers to the state veterinarians that supervise the process. Only one company presents a regulatory body that prepares the company to avoid management deficiencies, such as the training provided by the HCCP. It was verified in this study that regulatory bodies serve to eliminate and regulate certain deficiencies in the supply chain, that is, to reduce risks to human health, thus these regulated sectors are entitled to certification to prevent counterfeiting [67].

In this case, the supply chain has to be able to overcome disruptions caused by natural phenomena [6] that the same, created outside [10], cause vulnerability in it. Systems have to recover from these phenomena to stabilise in the initial situation [4].

Table 4. Summary of results of supply chain vulnerabilities.

	Product Characteristics and Whether It Amplifies Disruptive Activity	Supply Chain	Amplifier Feature for Disruptive Activities	Role of Suppliers in Disruptive Activity	Role of Suppliers	Effect of Management Decisions during an Interruption	Role of Regulatory Bodies
Company A	<ul style="list-style-type: none"> - Product confectioned moments before delivery. - Willingness to innovate in terms of machinery, to shorten the cooking time 	<ul style="list-style-type: none"> - Producers or suppliers contact the company - Delivery deadlines established - Delivery by carriers - Storage of raw material - Transformation of the raw material into the final product 	<ul style="list-style-type: none"> - Expiration of products - Higher margin of error since the final product is executed by labour 	Does not have a role in disruptive activity. Since the products are raw materials, they cannot innovate	Does not have a role	Joint communication facilitates the resolution of the disruptive activity	Supervision of frauds and management deficiencies (ASAE)
Company B	Sensitive products, such as vegetables, with very limited shelf life and open to innovations	<ul style="list-style-type: none"> - Weekly orders, established by deadlines - Reception of the plants by the transporter - Planting and treatment of the plants - Final product - Final consumer 	No magnifying feature whatsoever	The supplier does not have a role	Suppliers do not have any role in this situation.	Communication with suppliers	To avoid these frauds, HCCP provides training
Company C	Products that require refrigeration and are open to innovations	<ul style="list-style-type: none"> - Daily orders - Receiving live cattle at transporters - Storage of cattle - Slaughtering and processing of livestock - Own transport to customers - At customers' locations, as butchers are sold to the final consumer 	There are no magnifying resources.	Suppliers do not have a role	They do not have any role.	Communication with all agencies in the supply chain	<ul style="list-style-type: none"> - State Veterinarians, guarantee the legality of the process of collection and slaughter of animals; - ASAE supervises and inspects the company
Company D	Perishable horticultural and fruit products, with the possibility of innovation	<ul style="list-style-type: none"> - The company contacts the producers - Reception of products - Storage of fruit and vegetable products - Sale of the products to wholesalers and final consumers 	Delivery time, since they are perishable products, if they are not delivered on the due date, the products spoil	Does not have a role	Does not have a function	The company believes that its management decisions do not affect in the event of a disruption	Ensure the safety of public health
Company E	Products made in-house, with the possibility to innovate	<ul style="list-style-type: none"> - Producers (who make the products) - Suppliers who deliver the products to the bakery through their transporters - They store the products - Some are processed, and others resold - Delivery to the final consumer 	<ul style="list-style-type: none"> - Conservation; - Expiration date - Mismanagement 	The role is to deliver the feeds needed to make this innovation happen	At the time of the innovation of the fradinhas (new cake made in the company), they had to deliver flour	Good connections with employees and suppliers	Ensure the conservation of products so as not to affect the well-being of final consumers

4.3. Resilience in the Supply Chain

The resilience in the supply chain, explicit in Table 5, goes through strategies to prepare and respond to an interruption. All companies report having strategies, where communication and alternative producers or suppliers stand out, where three companies report that it affects customer satisfaction and two companies report optimising time [64,66].

The five companies all highlight resources and process enablers during this event, namely alternative products and suppliers or using products from companies in areas near the companies' location. Four companies, A, B, C and D, have meetings to obtain information from stakeholders, and three companies, B, C, D and E, still incorporate daily phone calls. All companies have information-sharing activities with the other companies [66]. Regarding the competitive position, two of the companies, A and B, intend to ensure market share. Three refer to differentiation in the reduction of time in the preparation of dishes, another company refers to the good management of stock, and lastly, one company refers to the diversification of products [62,63].

All of the companies present the ability to obtain products at the time of disruptive activity, as well as available suppliers. Lastly, obstacles, mainly the COVID-19 pandemic, were referred to by three companies. Company B referred to Brexit and the difficulty in delivering by deadlines since the borders were closed during that time. In a contradictory way, the literature states that the European Union loses little with these types of situations [68]. Finally, four companies present ways to improve the supply chain in disruptive activity through greater knowledge of innovative processes or products by suppliers. Only Company E refers that there are no ways to improve. The operational part appears in the literature as the area in the supply chain that needs improvement [69].

Table 5. Summary of results of resilience in the supply chain.

	Strategies for Responding to Interruptions	Resources that Support the Disruptive Event	Effect of Strategies on Interruption	the Competitive Position of the Company	Process of Obtaining Information from Stakeholders	Ability to Obtain Product over a Disruptive Activity	Available Suppliers	Obstacles	How to Better Prepare a Supply Chain
Company A	- Identical products - Substitution with another product	Resort to companies in the company's area	Time optimisation	Product quality at a low price, in a short time of production	- Individual Meetings - Collective meetings	- Alternative Products - Contact with suppliers	Yes, since they are large suppliers, that is, with great capacity	Increase in raw materials due to COVID-19	Increased supplier communication about innovative processes
Company B	- Remodeling of the delivery procedure - Identical products	Daily contact with intermediaries	Satisfied customers	Securing market share	- Weekly meetings - Daily phone calls	Regular contacts and good relationships with suppliers to obtain the product	Yes. Some suppliers are always able to deliver immediately	Brexit, with the closing of the borders between France and England	Increased supplier knowledge of innovative planting procedures horticultural and fruit treatment
Company C	- Communications - Alternative suppliers	Alternative suppliers	- Optimise time - Achievement of stipulated deadlines	Assure customers by supplier alternatives	Meetings with stakeholders	A good relationship with suppliers	Yes, depending on the product	COVID-19	Communication with stakeholders to seek innovative ideas either for products or processes
Company D	- Contacting Customers - Alternative Solutions	Producers have alternative supplies	The customer is not affected	Existence of diversity of producers	Permanent contact with stakeholders	Search for alternative producers	Yes	Difficulty in delivery times or product maturity	You cannot prepare in a better way because your products have no innovative solution.
Company E	Have stock	The company is branched into four establishments, so they supply each other in this case	The decreased risk with customer satisfaction	The competitive position of differentiation, by the issue of never lacking product	- Phone calls when necessary - Quarterly meetings	Product alternative	Diversified and available suppliers	COVID-19	With effective stakeholder communication, we can access innovative ideas that can cover the various areas

5. Conclusions

The present study examined the supply chain in specific companies in the food sector during the COVID-19 pandemic, identified potential problems and pointed out solutions to those problems. The study aims to address the functioning of the supply chain, to integrate the components of vulnerability and resilience, taking into account that good management of the supply chain of companies can increase their competitive advantage.

The main conclusion that can be highlighted is that the interviewed companies are mostly companies that belong to SMEs, which makes them not have a formalised supply chain, unlike large companies, and is later reflected in the lack of metrics. It was also evident that the COVID-19 pandemic affected the companies' supply chains in a harmful way since several delays in the supply of products during that period. In addition to all this, the fact that these companies have smaller budgets forces them to look for solutions, such as constantly seeking low-cost suppliers and maintaining quality, which consequently does not allow the company to maintain long-term relationships with them. Finally, it is also possible to conclude that most companies under study have the same difficulties in solving the interruptions, i.e., the lack of alternative suppliers that can guarantee the same quality in the products.

All companies present several aspects that can be improved. Among them is that many of them identify that suppliers have no function or role in an activity seen as disruptive. In this way, companies could improve this aspect by seeking innovative solutions for their products from their suppliers. They can also improve their supply chain by identifying new suppliers. It would be important to unify all the management in one system because it is important to choose an efficient management system to facilitate the visualisation of each step of the process and improve its supply chain. Another aspect that can always be improved is the greatest possible integration of the whole team involved in the chain. With aligned teamwork, it is possible to reduce operational costs, improve process productivity and manage stock to benefit the entire supply chain. It could be good for companies to analyse previous results (their history) better since this action enables managers to prepare for unforeseen or future failures.

The study's practical implications would be very interesting and valuable for companies to opt for new practices, such as establishing new partnerships. A good example would be to establish partnerships with companies that deliver orders from a smartphone application. These applications usually deliver food, pharmacy products, or even super-market products. It is an easy way to connect sellers and consumers through couriers who drive the order to the consumer's desired location. Since the companies in this study are all food companies, it would be an added value. From these applications, the companies would reach a larger number of people and consequently make more sales and increase their turnover. SMEs and their employees must adapt to the use of information technology tools and enjoy the advantages of working in a network and a virtual environment. There must be a better use of digital platforms available for this purpose and that best suit their business. These tools should favour the facilitation of communication with customers, cost reduction and business profitability.

Concerning theoretical implications, it can be said that there is very little literature on supply chains in SMEs. This study is important to contribute to the literature of supply chains in SMEs in times of pandemic or crisis. This study compares several companies in the food sector and sellers of perishable products, providing additional value, given the existing scarcity of studies among several companies.

It is also important to mention that this study is original because few studies on this theme applied to SMEs and in the Portuguese context. We highlight that they are all food sector companies, which allows us to make certain comparisons between the companies and understand certain differences between them and their respective supply chains.

Finally, in this study, we present some limitations and indicate possible recommendations for future lines of research. There are always limitations in the study that prevent us from obtaining the maximum and highest quality information possible. One limitation of

case studies is that their results cannot be generalised since the present study was applied to specific companies in a specific context. Therefore, we have to stick only to the specific situations and not generalise. Another limitation is the interviewees' interpretation of the interview. The fact that the interview script used has technical terms that many times the interviewees may not understand or are even terms that they do not encounter daily makes it difficult for the interviewees to interpret the meaning, which may lead to a less adequate interpretation of the information and is usually not the information intended by the interviewers. Since the study was conducted during the COVID-19 pandemic, it made the whole process of conducting interviews with more companies difficult.

Although the objective of the present study is ambitious, its fulfillment may point to the need for a greater deepening of the themes under consideration. Issues such as disorders, vulnerabilities and resilience in supply chains can be studied in isolation and in greater depth. To this end, it is suggested that future studies should focus on each of these themes.

In future studies, we also suggest developing other lines of research, not only in a larger number of companies, for example, instead of analysing only SMEs, also analyse micro and large companies. It would be interesting to understand how many existing metrics different companies present to overcome a supply chain disruption. In this way, new metrics that some companies use are made known to other companies, which can support the good functioning of the supply chain within a company. Moreover, as a suggestion for future studies, it would be important to know the characteristics of supply chains, their connections from the point of view of vulnerabilities and the strength and direction of the environmental impact on their resilience. To conclude, we leave some research questions for future studies: Are SMEs able to have a formalised supply chain given their limited resources? What are the effects of supply chain metrics when applied to SMEs?
